Congruent and incongruent processing in the Y-maze based on latent sequence learning of inter-trial associations. The study examined the congruency and latent sequence hypotheses regarding location and time as learning factors in two previous experimental tasks designed to test for associative learning based on spatial and temporal cues. In the first task, in which there was sufficient time for learning, there was a significant facilitation for trials involving repetitions of the cues, but not for trials involving different cues. This pattern of results was similar to that of a previous study on motor learning and found to be consistent with the congruency hypothesis. A new, two-stage Y-maze task was used, in which a target (nosepip) odor was applied as a location cue. In the second task, there was again a significant facilitation for trials involving repetitions of cues, and no facilitation for trials involving nonrepetitions. Although this pattern is consistent with the congruency hypothesis, it is also consistent with the latently learned sequence hypothesis; in this case, the hypothesis that a fixed, previously learned location-cue sequence is activated even on trials involving a repeated cue. These results provide support for a temporal bias in associative learning that arises as a function of association strength in complex-cue-learning tasks. The results also suggest that the Y-maze task may be more appropriate than the classical conditioning procedures for measuring cue repetition effects.
